

Multi-Tenancy Architecture

The term “Multi-Tenancy” refers to a software architecture in which a single instance of software runs on a server and serves multiple tenants.

Tenants are a group of users who share a common access with specific privileges to a software instance, including its data, configuration, management, tenant-specific functionality, and non-functional properties.

Multi-Tenancy architectures cut costs by allowing vendors to patch and update the software for many users simultaneously, while also allowing many users to share the underlying infrastructure.
